

# Disks

---

pmli

# Outline

---

- Interfaces
- Geometry
- Add new disks
  - Installation procedure
  - Filesystem check
  - Add a disk using sysinstall
- RAID
  - GEOM
- Appendix – SCSI & SAS

# Disk Interfaces

- SCSI
  - Small Computer Systems Interface
  - High performance and reliability
- IDE (or ATA)
  - Integrated Device Electronics (or AT Attachment)
  - Low cost
  - Become acceptable for enterprise with the help of RAID technology
- SATA
  - Serial ATA
- SAS
  - Serial Attached SCSI
- USB
  - Universal Serial Bus
  - Convenient to use

Expensive!  
SCSI Card ~ 10k

Low Price!

Enhancement

Speeds up!

# Disk Interfaces – ATA & SATA

#### ATA (AT Attachment)

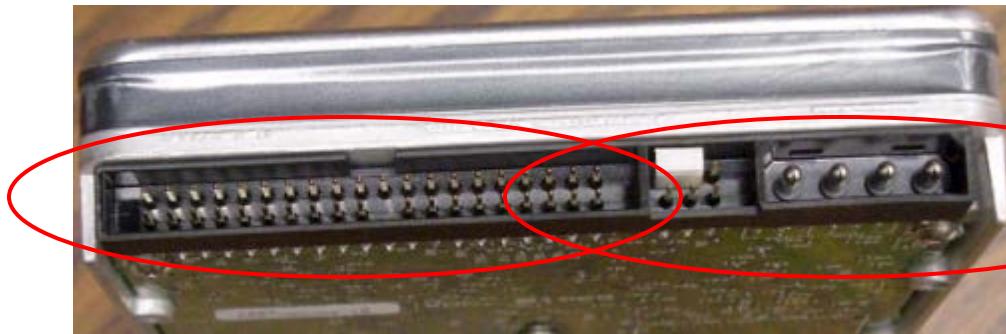

- ATA2
    - PIO, DMA
    - LBA (Logical Block Addressing)
  - ATA3, Ultra DMA/33/66/100/133
  - ATAPI (ATA Packet Interface)
    - CDROM, TAPE
  - Only one device can be active at a time
    - SCSI support overlapping commands, command queuing, scatter-gather I/O
  - Master-Slave
    - Primary Master (0)/Slave(1)
    - Secondary Master(2)/Slave(3)
  - 40-pin ribbon cable

SATA

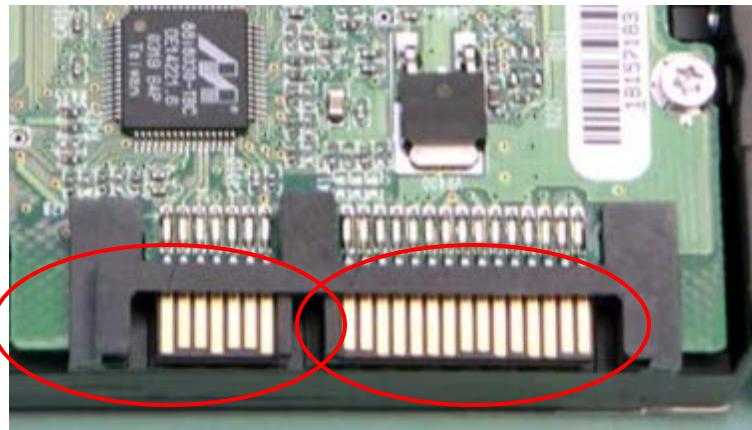

- Serial ATA
  - SATA-1 1.5Gbit/s, SATA-2 3Gbit/s, SATA-3 6GBit/s

# Disk Interfaces – ATA & SATA Interfaces

- ATA interface and it's cable

- SATA <sup>Data</sup> interface and it's cable

Data

Power

# Disk Interfaces – USB

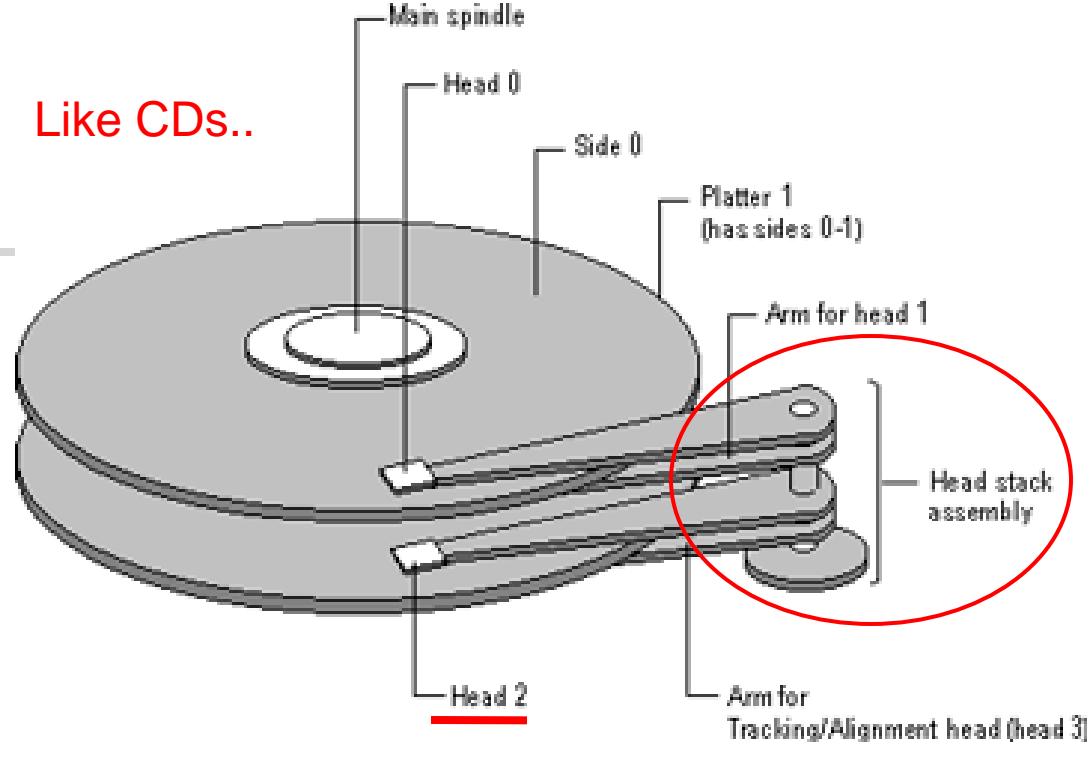

- IDE/SATA to USB  
Converters

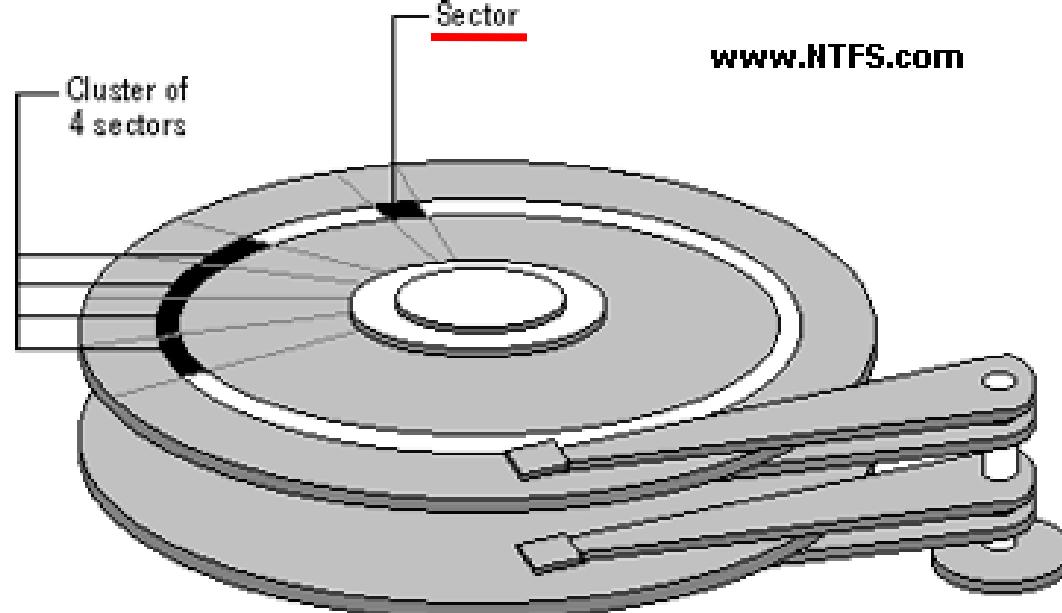

# Disk Geometry (1)

Like CDs..

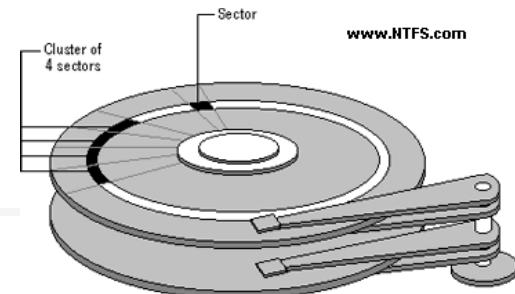

- sector
  - Individual data block
- track
  - circle
- cylinder
  - circle on all platters
- Position
  - **CHS:**  
Cylinder,  
Head (0, 1, ...),  
Sector

[www.NTFS.com](http://www.NTFS.com)

# Disk Geometry (2)

## ❑ 40G HD

- 4866 cylinders, 255 heads
- 63 sectors per track, 512 bytes per sector
- $\underline{512} * \underline{63} * \underline{4866} * \underline{255} = \underline{40,024,212,480}$  bytes
  - G M K
- 1KB = 1024 bytes
- 1MB = 1024 KB = 1,048,576 bytes
- 1GB = 1024 MB = 1,073,741,824 bytes
- $40,024,212,480 / 1,073,741,824 \doteq \underline{37.275}$  GB

Why?

10<sup>3</sup> vs. 2<sup>10</sup>...

# Disk Installation Procedure (in BSD...)

---

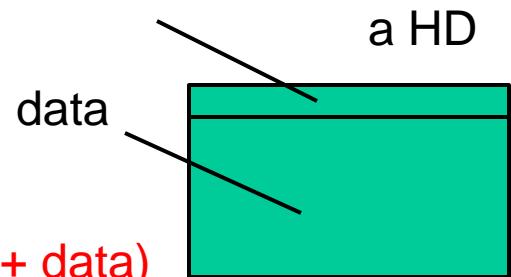

# Disk Installation Procedure (1)

□ The procedure involves the following steps:

- Connecting the disk to the computer
  - IDE: master/slave
  - SATA
  - SCSI: ID, terminator
  - power
- Creating device files
  - Auto created by devfs
- Formatting the disk
  - Low-level format
    - Manufacturer diagnostic utility
    - **Kill all** address information and timing marks on platters
    - Repair bad sectors → mark the bad sectors and don't use them!

Please do it offline...

Meta data

Format (meta data + data)  
vs. fast format (data only)

# Disk Installation Procedure (2)

---

- Partitioning and Labeling the disk
  - Allow the disk to be treated as a group of independent data area
  - e.g. root, home, swap partitions
  - Former Suggestions:
    - /var, /tmp ➔ separate partition (for backup issue)
    - Make a copy of root filesystem for emergency
- Establishing logical volumes
  - Combine multiple partitions into a logical volume
  - Related to RAID
  - Software RAID technology
    - GEOM: geom(4)、geom(8)
    - ZFS: zpool(8)、zfs(8)、zdb(8)

# Disk Installation Procedure (3)

---

- Creating UNIX filesystems within disk partitions
  - Use “**newfs**” to install a filesystem for a partition
  - Establish all filesystem components
    - A set of inode storage cells
    - A set of data blocks
    - A set of superblocks
    - A map of the disk blocks in the filesystem
    - A block usage summary

# Disk Installation Procedure (4)

---

➤ Superblock contents

Software info.

- The length of a disk block
- Inode table's size and location
- Disk block map
- Usage information
- Other filesystem's parameters

SoftUpdate

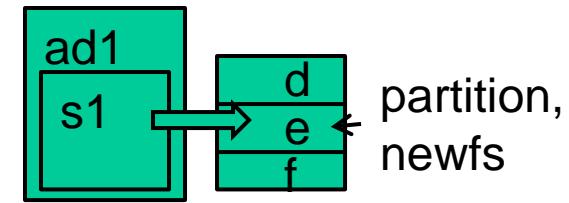

➤ sync

- The **sync()** *system call* forces a write of dirty (modified) buffers in the block buffer cache out to disk.
- The **sync utility** can be called to ensure that all disk writes have been completed before the processor is halted in a way not suitably done by reboot(8) or halt(8).

done automatically nowadays~ ☺

# Disk Installation Procedure (5)

- **mount**
  - Bring the new partition to the filesystem tree
  - mount point can be any directory (empty)
  - # mount /dev/ad1s1e /home2
- **Setting up automatic mounting**
  - Automount at boot time

Mount CD

Also for ISO img. file

```
/etc/fstab
% mount -t ufs /dev/ad2s1a /backup
% mount -t cd9600 -o ro,noauto /dev/acd0c /cdrom
```

Usually: 2, 1 for root;  
No write = 0

liuyh@NASA:/etc> cat fstab

# Device	Mountpoint	Fstype	Options	Dump	Pass#
/dev/ad0s1b	none	swap	sw	0	0
/dev/ad2s1b	none	swap	sw	0	0
/dev/ad0s1a	/	ufs	rw	1	1
/dev/acd0	/cdrom	cd9660	ro,noauto	0	0
/dev/ad2s1a	/backup	ufs	rw,noauto	2	2
<b>csduty:/bsdhome</b>	<b>/bsdhome</b>	<b>nfs</b>	<b>rw,noauto</b>	<b>0</b>	<b>0</b>

Mount from the network; talk about it in “NFS”...

# Disk Installation Procedure (6)

- Setting up swapping on swap partitions

- swapon, swapoff, swapctl
- swapinfo, pstat

e.g. `swapon -a` // mount all partitions for swap usage

```
17:05 pml1@bsd5 [~] >swapinfo
Device           1K-blocks   Used   Avail Capacity
/dev/label/swap-0    1048572   60372  988200      6%
/dev/label/swap-1    1048572   59808  988764      6%
Total            2097144  120180 1976964      6%
17:05 pml1@bsd5 [~] >
```

## fsck – check and repair filesystem (1)

- System crash will cause
    - Inconsistency between memory image and disk contents
  - fsck
    - Examine all local filesystem listed in /etc/fstab at boot time. (fsck -p)
    - Automatically correct the following damages:  
➤ Unreferenced inodes  
➤ Inexplicably large link counts  
➤ Unused data blocks not recorded in block maps  
➤ Data blocks listed as free but used in file  
➤ Incorrect summary information in the superblock  
➤ fsck(8) 、 fsck\_ffs(8)  
➤ ffsinfo(8): dump metadata
- auto. Do it at boot time
- check if filesys. is clean...  
0 dirty (rw) 1 clean (ro)

## fsck – check and repair filesystem (2)

- Run fsck in manual to fix serious damages
    - Blocks claimed by more than one file
    - Blocks claimed outside the range of the filesystem
    - Link counts that are too small
    - Blocks that are not accounted for
    - Directories that refer to unallocated inodes
    - Other errors
  - fsck will suggest you the action to perform
    - Delete, repair, ...
- No guarantee on  
fully recover you HD...

# Adding a disk to FreeBSD (1)

## 1. Check disk connection

- > Look system boot message

```
ad3: 238475MB <Hitachi HDS722525VLAT80 V36OA6MA> at ata1-slave UDMA100
```

Line, speed

## 2. Use /usr/sbin/sysinstall to install the new HD

- > Configure → Fdisk → Label
  - > Don't forget to "W" the actions
  - > Easiest approach, but has some problems.
- > fdisk(8), bslabel(8), newfs(8)

## 3. Make mount point and mount it

- > # mkdir /home2
- > # mount -t ufs /dev/ad3s1e /home2
- > # df

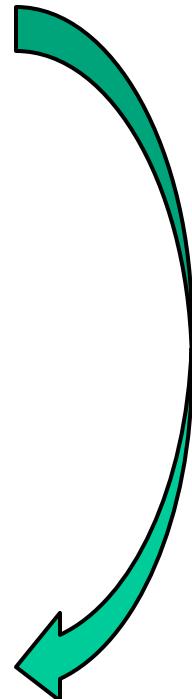

## 4. Edit /etc/fstab

# Adding a disk to FreeBSD (2)

□ If you forget to enable soft-update when you add the disk

- % umount /home2
- % tunefs –n **enable** /dev/ad3s1e
- % mount –t ufs /dev/ad3s1e /home2
- % mount

```
/dev/ad0s1a on / (ufs, local, soft-updates)
/dev/ad1s1e on /home (ufs, local, soft-updates)
procfs on /proc (procfs, local)
/dev/ad3s1e on /home2 (ufs, local, soft-updates)
```

# RAID

---

# RAID – (1)

## □ Redundant Array of Inexpensive Disks

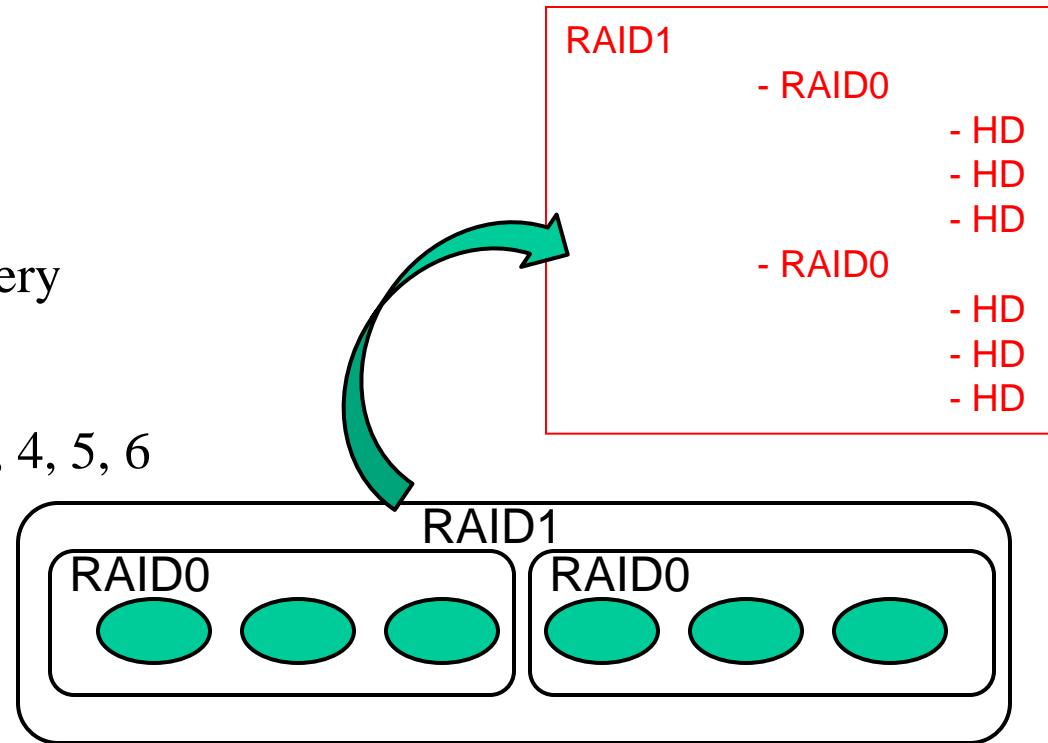

- A method to combine several physical hard drives into one logical unit  
e.g. HD1, HD2 → D:\ in windows

## □ Depending on the type of RAID, it has the following benefits:

- Fault tolerance
- Higher throughput
- Real-time data recovery

## □ RAID Level

- RAID 0, 1, 0+1, 2, 3, 4, 5, 6
- Hierarchical RAID

# RAID – (2)

---

## □ Hardware RAID

- There is a dedicate controller to take over the whole business
- RAID Configuration Utility after BIOS
  - Create RAID array, build Array

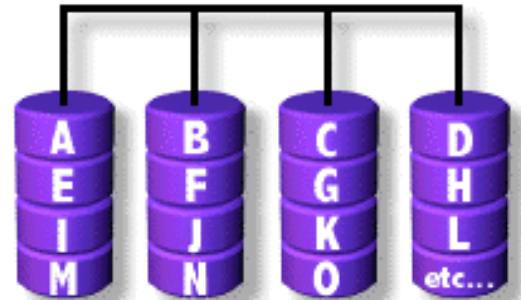

## □ Software RAID

- **GEOM**
  - **CACHE**、**CONCAT**、**ELI**、**JOURNAL**、**LABEL**、**MIRROR**、**MULTIPATH**、**NOP**、**PART**、**RAID3**、**SHSEC**、**STRIPE**、**VIRSTOR**
- **ZFS**
  - **JBOD**、**STRIPE**
  - **MIRROR**
  - **RAID-Z**、**RAID-Z2**、**RAID-Z3**

# RAID 0 (normally used)

(500GB+500GB=1TB)

- Stripped data intro several disks
- Minimum number of drives: 2
- Advantage
  - Performance increase in proportional to n **theoretically**
  - Simple to implement
- Disadvantage
  - No fault tolerance
- Recommended applications
  - Non-critical data storage
  - Application requiring high bandwidth (such as video editing)

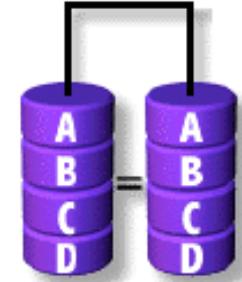

e.g. HD1 (500GB), HD2 (500GB)  
→ D:\ in windows (1TB)

parallel file io from/to different HDs

# RAID 1 (normally used)

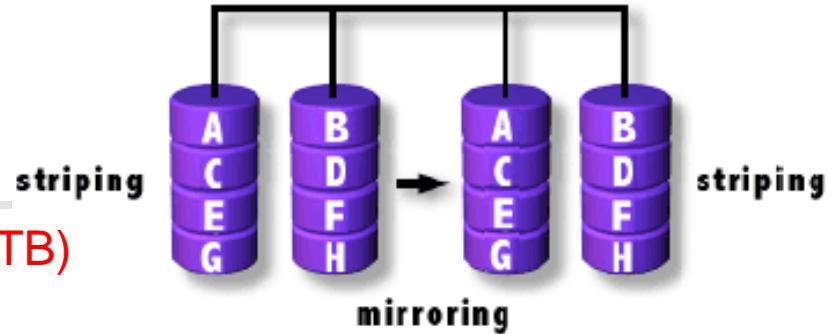

(500GB+500GB=500GB)

- Mirror data into several disks
- Minimum number of drives: 2
- Advantage
  - 100% redundancy of data
- Disadvantage
  - 100% storage overage
  - Moderately slower write performance
- Recommended application Cause by double check mechanisms on data...
  - Application requiring very high availability (such as home)

## RAID 0+1 (normally used)

$[(500\text{GB}+500\text{GB})+(500\text{GB}+500\text{GB})]=1\text{TB}$

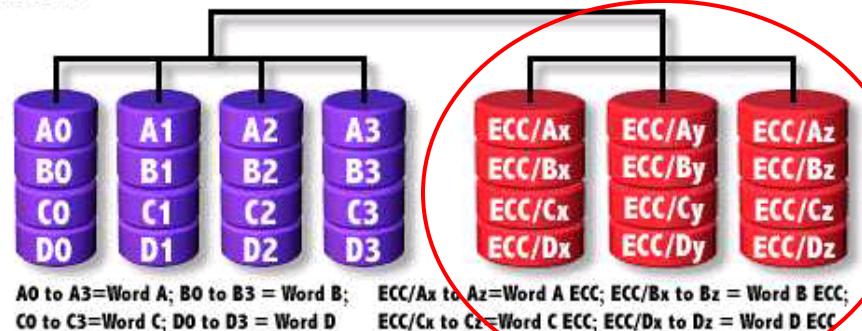

- Combine RAID 0 and RAID 1
- Minimum number of drives: 4

RAID1, RAID1  
Them RAID0 above it

# RAID 2

RAID 2

- Hamming Code ECC Each bit of data word

- Advantages:

- "On the fly" data error correction

Read, check if correct, then read

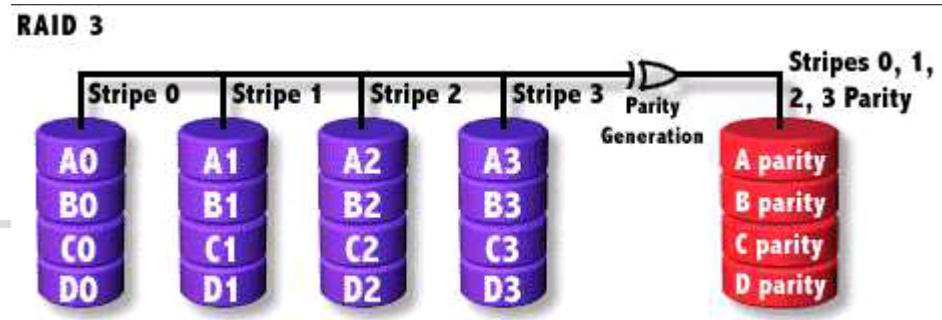

- Disadvantages:

- Inefficient
- Very high ratio of ECC disks to data disks

- Recommended Application

- No commercial implementations exist / not commercially viable

# RAID 3

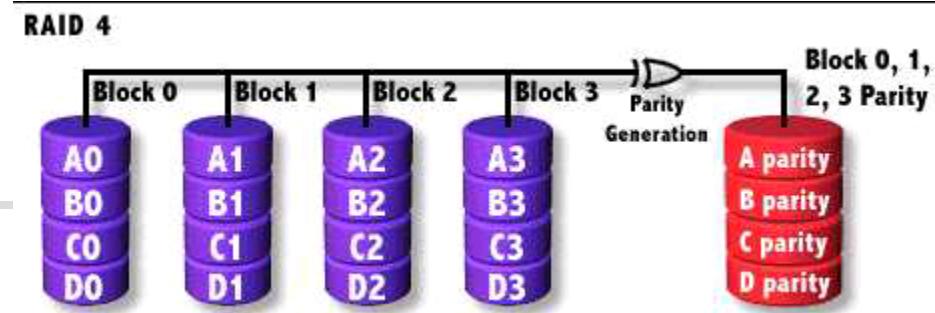

RAID1 if two HDs

Save parity

- Parallel transfer with Parity
- Minimum number of drives: 3
- Advantages:
  - Very high data transfer rate
- Disadvantages:
  - Transaction rate equal to that of a single disk drive at best
- Recommended Application
  - Any application requiring high throughput

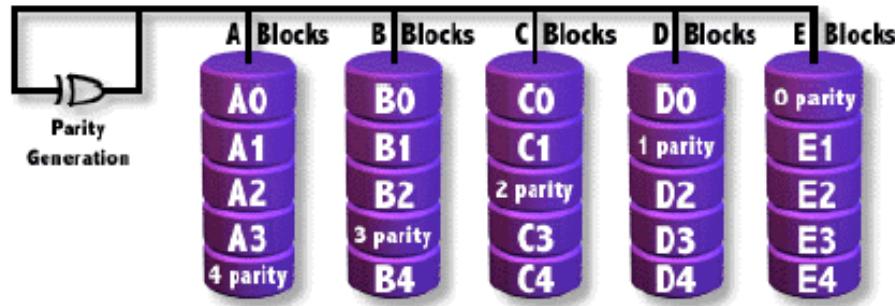

# RAID 4

- Similar to RAID3
- RAID 3 V.S RAID 4
  - Byte Level V.S Block Level
  - Block interleaving
    - Small files (e.g. 4k)

Block normally 512bytes (4k for WD HDs)

# RAID 5 (normally used)

- Independent Disk with distributed parity blocks

- Minimum number of drives: 3

Origin from RAID3

- Advantage **Parallel file I/O**

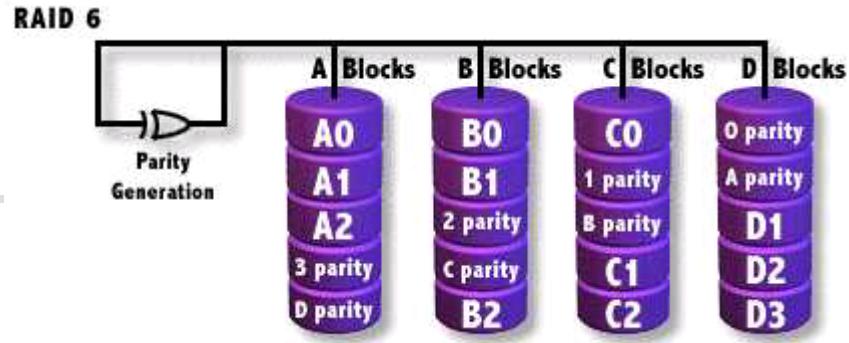

- Highest read data rate
  - Medium write data rate

- Disadvantage

- Disk failure has a medium impact on throughput
  - Complex controller design
  - When one disk failed, you have to rebuild the RAID array

Can tolerate only 1 HD failure

# RAID 6 (normally used)

- Similar to RAID5
- Minimum number of drives: 4
- 2 parity checks, 2 disk failures tolerable.

Slower than RAID5 because of storing 2 parities...

# GEOM

---

Modular Disk Transformation Framework

# GEOM – (1)

---

## □ Support

- ELI – geli(8): cryptographic GEOM class
  - JOURNAL – gjournal(8): journaled devices Journalize (logs) before write
  - LABEL – glabel(8): disk labelization
  - MIRROR – gmirror(8): mirrored devices
  - STRIPE – gstripe(8): striped devices Software RAID1  
Software RAID0
  - ...
- 
- <http://www.freebsd.org/doc/handbook/geom.html>

## GEOM – (2)

### □ GEOM framework in FreeBSD

- Major RAID control utilities
- Kernel modules (`/boot/kernel/geom_*`)
- Name and Providers   devices

Logical  
volumes

- “manual” or “automatic”
- Metadata in the last sector of the providers

### □ Kernel support

(1) On demand load/unload kernel modules..

- {glabel,gmirror,gstripe,g\*} load/unload
  - device `GEOM_*` in kernel config
  - `geom_*_enable=“YES”` in `/boot/loader.conf`

(2) Build-in kernel and recompile

(3) load automatically at booting

# GEOM – (3)

## □ LABEL

Why us it? → bundle by name instead of bundle by provider

- Used for GEOM provider labelization.
- Kernel
  - device GEOM\_LABEL
  - geom\_label\_load="YES"
- glabel (for new storage)
  - # glabel label -v usr da2
  - # newfs /dev/label/usr
  - # mount /dev/label/usr /usr
  - # glabel stop usr
  - # glabel clear da2
- UFS label (for an using storage)
  - # tunefs -L data /dev/da4s1a
  - # mount /dev/ufs/data /mnt/data

e.g. ad0s1d → usr

Label → auto. at boot

>> Create → only this time

/dev/label/usr

Stop using the name

Clear metadata on provider

"data" is a name

# GEOM – (4)

## □ MIRROR

- Used for GEOM provider labelization.
- Kernel
  - device GEOM\_MIRROR
  - geom\_mirror\_load=“YES”
- gmirror     **⌘ Using gmirror for building up RAID1**
  - # gmirror label -v -b round-robin data da0
  - # newfs /dev/mirror/data       **logical volume called “data”, using HD: da0, ...**
  - # mount /dev/mirror/data /mnt
  - # gmirror insert data da1       **Add in HD**
  - # gmirror forget data       **Kill inexist HDs**
  - # gmirror insert data da1
  - # gmirror stop data
  - # gmirror clear da0

# GEOM – (5)

---

## □ STRIPE

- Used for GEOM provider labelization.
- Kernel
  - device GEOM\_STRIPE
  - geom\_stripe\_load=“YES”
- gstripe
  - # gstripe label -v -s 131072 data da0 da1 da2 da3
  - # newfs /dev/stripe/data
  - # mount /dev/stripe/data /mnt
  - # gstripe stop data
  - # gstripe clear da0

← Create logical volume “data”,  
which stripe da0~da3 HDs
